

MedPath — Sample Patient Data

Two synthetic patients, ready to paste into your app as plain text or a Python dictionary. Each has a background, a symptom timeline, lab results, medicines, and one deliberately missing test that your app should flag.

PATIENT 1 — Priya Menon, 34, Female

Background: Works a desk job, mother of one, no major past medical history. Came to a primary health clinic complaining of ongoing tiredness.

Symptom Timeline:

3 months ago: Started feeling more tired than usual, especially by afternoon. Assumed it was work stress.

2 months ago: Noticed she gets breathless climbing stairs, which never happened before. Mild headaches a few times a week.

5 weeks ago: Visited local clinic. Reported fatigue and breathlessness. Doctor noted pale inner eyelids on examination.

5 weeks ago: Basic blood test (CBC) was ordered.

3 weeks ago: Started taking an over-the-counter multivitamin on her own, no improvement.

Today: Reports dizziness when standing up quickly, in addition to ongoing fatigue.

Lab Results on File:

5 weeks ago — Complete Blood Count (CBC):

Hemoglobin: 9.2 g/dL (Low — normal range 12–15.5 g/dL for women)

MCV (mean cell volume): 72 fL (Low — normal range 80–100 fL, suggests small red blood cells)

White blood cell count: Normal

Platelet count: Normal

Medications:

Over-the-counter multivitamin tablet, once daily, self-started 3 weeks ago (not prescribed by a doctor)

No other regular medications

⚠ Missing Test (built-in gap): No **iron studies** (serum ferritin / serum iron / TIBC) have ever been ordered, despite a low hemoglobin AND low MCV — a classic combination that should prompt a doctor to check iron levels before assuming the cause. This is the gap your app should flag: *"Low Hb + low MCV present — no ferritin/iron panel on record."*

What a good AI hypothesis output should surface:

Top hypothesis: Iron-deficiency anemia (supported by: low Hb, low MCV, fatigue, breathlessness, pallor)

Missing test flagged: Serum ferritin / iron studies

Recommended next step: Order iron studies to confirm and rule out other causes of anemia (e.g., chronic disease, other deficiencies)

PATIENT 2 — Arjun Rao, 47, Male

Background: Runs a small shop, sedentary lifestyle, father had type 2 diabetes. No current diagnosed conditions. Visited clinic for a routine check-up plus a few complaints he almost didn't mention.

Symptom Timeline:

4 months ago: Started noticing he's thirstier than usual, drinking more water throughout the day.

3 months ago: Needing to urinate more frequently, including waking up at night 1–2 times to use the bathroom.

2 months ago: Noticed blurry vision occasionally, especially by evening. Assumed it was just eye strain from screens.

6 weeks ago: Routine check-up at clinic. Blood pressure and weight recorded. Mentioned thirst and frequent urination briefly to the doctor.

6 weeks ago: A **fasting blood glucose** test was ordered as a general check.

Today: Comes back reporting the blurry vision has continued and he's noticed a small cut on his foot is healing slower than usual.

Lab Results on File:

6 weeks ago — Fasting Blood Glucose: 118 mg/dL (Borderline/elevated — normal fasting is under 100 mg/dL; 100–125 mg/dL is considered prediabetic range)

6 weeks ago — Blood Pressure: 138/86 mmHg (Mildly elevated)

6 weeks ago — Weight/BMI: BMI 29.4 (Overweight range)

Medications:

None currently prescribed

No supplements

⚠ Missing Test (built-in gap): No **HbA1c** (average blood sugar over 3 months) has ever been ordered, despite a borderline fasting glucose, a family history of diabetes, classic symptoms (thirst, frequent urination, blurry vision), and a slow-healing wound — all of which together are strong reasons to check HbA1c before concluding it's "just borderline." This is the gap your app should flag: *"Elevated fasting glucose + classic symptoms + family history — no HbA1c on record."*

What a good AI hypothesis output should surface:

Top hypothesis: Type 2 diabetes / prediabetes (supported by: elevated fasting glucose, thirst, frequent urination, blurry vision, slow-healing wound, family history, overweight BMI)

Missing test flagged: HbA1c

Recommended next step: Order HbA1c to confirm diabetes status and guide next steps
